

# Navigation of Flagellated Micro-Swimmers

Laetitia Girdali

with C. Van Landeghem, L. Berti, C. Prud'homme, R. Chesneaux, Z.  
El Khiyati and J. Bec

July, 2023

# Challenges of micro-swimming

- ▶ Medical applications : driving micro-robots through our body
- ▶ Multidisciplinary fields (Maths, Physics , Biology and Robotic)
- ▶ Biomimetism

# Controlling

**Locomotion** : Design realistic, complicated model (elasticity, fluid-structure interactions, etc.)

⇒ find optimal gait for displacement

Alouges et al. (2013), Ghaffari et al. (2015), Loheac et al. (2015), Berti et al. (2021) ...

**Navigation** : travel in a complex environment with simple models for displacement

⇒ find optimal path to rapidly reach a target

Gustavsson et al. (2017), Biferale et al. (2019), Liebchen and Lowen (2019), Alaghesan et al. (2020) ...

Usually treated separately, assuming large separation of scales

# Prescribed deformation - Navier-Stokes

$$\left\{ \begin{array}{ll} \rho(\partial_t u|_{\mathbb{A}_t} + (u - u_{\mathbb{A}_t}) \cdot \nabla u) - \mu \Delta u + \nabla p = 0, & \text{in } \mathcal{F}_t, \\ \nabla \cdot u = 0, & \text{in } \mathcal{F}_t, \\ u = U \circ \mathbb{A}_t, & \text{on } \partial \mathcal{N}_t, \\ m \dot{\mathbf{v}} = -F_{fluid} + F^{int}, \\ J \dot{\Omega} = -M_{fluid} + M^{int}, \end{array} \right.$$

$$U := \underbrace{\mathbf{v} + \Omega \times (x - x^{CM}(t))}_{\text{rigid motion}} + \overbrace{u_d(t)}^{\text{deformation}}$$

- For  $u_d$  prescribed  
 $\Rightarrow$  the rigid motion ( $\mathbf{v}$  and  $\Omega$ )  
 are computed.

# Arbitrary Lagrangian Eulerian framework

$$A_t = \mathbb{I} + \phi_t$$

$\phi_t$  :: swimmer's deformation and an harmonic extension elsewhere

**ALE map** describing the evolution of the computational domain

# Numerical methods

- ▶ Classical ALE framework [Maury, 2000]
- ▶ Time discretization
- ▶ Spatial discretization → conforming Lagrange finite elements
- ▶ Moving domain → Arbitrary-Lagrangian-Eulerian technics
- ▶ Mesh (using MMG)
  - ▶ Mesh quality indices
  - ▶ Re-meshing metric → distance to the swimmer
  - ▶ Interpolating
- ▶ Feel++

## Algebraic strategy

$$\underbrace{\mathcal{P}^T A \mathcal{P}}_A \begin{bmatrix} \mathbf{u}_I \\ \mathbf{u}_\Gamma \\ \mathbf{U} \\ \omega \\ \rho \end{bmatrix} = \mathcal{P}^T \begin{bmatrix} G_I \\ G_\Gamma \\ 0 \\ 0 \\ 0 \end{bmatrix}.$$

- ▶ Requires efficient implementation of  $\mathcal{P}^T A \mathcal{P}$  in parallel
- ▶ Use a block preconditioner of type PCD or PMM

# Micro-swimmers deformation gait

The deformation can be modeled by defining the deformation velocity  $u_d$  on the boundary of the swimmer.

**Spermatozoon** :  $u_d$  for a sinusoidal pl:

$$u_d(t, x) = \begin{bmatrix} A_1 \cos(4\pi(t - x)) \\ A_2 \cos(2\pi(t - x)) \\ 0 \end{bmatrix}$$

where  $A_1, A_2$  define the amplitudes.

**Multi-sphere swimmers** :

$u_d$  : : relative speed between the spheres.

# Numerical simulations

## Spermatozoon

## Three-sphere swimmer

## Three-sphere swimmer planar

Feel++ Youtube channel [<https://www.youtube.com/@FeelppOrgChannel>]  
Feel++ [<https://github.com/feelpp/feelpp>]

# Lubrication forces and torques

- ▶ Short-range repulsive force [R. Glowinski et al.]
- ▶ Activated when the distance between two bodies is less than  $\rho$
- ▶ Prevent the bodies overlapping and direct contacts

$$F^{int} = \begin{cases} 0, & \text{for } d_{ij} > \rho, \\ \frac{1}{\varepsilon} \overrightarrow{X_i X_j} (\rho - d_{ij})^2, & \text{for } 0 \leq d_{ij} \leq \rho. \end{cases} \quad T^{int} = -\overrightarrow{X^{CM} X_i} \times F^{int},$$

# Computation of the distance function

- ▶ Distance  $D(x) : \mathbb{R}^3 \rightarrow \mathbb{R}$  compute on the grid
- ▶  $\Rightarrow$  Costly !!
- ▶ Narrow band fast marching method
- ▶  $D$  is computed **only near the neighborhood around front**

## Narrow band fast marching method

# Fast marching method performance

Threshold $d_{max}$	Execution time in 2D	Speedup
1.9	1.959 s	1.0
1.0	0.722 s	2.71
0.5	0.411 s	4.76
0.25	0.316 s	6.20
0.125	0.276 s	7.09
0.0625	0.261 s	7.50

Threshold $d_{max}$	Execution time in 3D	Speedup
1.9	22.851 s	1.0
1.0	5.869 s	3.89
0.5	2.368 s	9.65
0.25	1.815 s	12.59
0.125	1.759 s	12.99

► ⇒ The band should be narrow !

# Collision simulations

## Particles in a 2D symmetric stenotic artery

## Zebra fish artery network

## Multi-sphere falling down

## Sum up

- ▶ **Swimmer dynamics** in a complex environment is **very costly**
- ▶ Optimize in this framework is a challenging task
- ▶ Less accuracy dynamics could help
- ▶ The importance of selecting the right optimization tools

Could machine learning help?

## 2. Locomotion + Navigation through Reinforcement Learning

Steering undulatory micro-swimmers in a moving fluid through reinforcement learning

Joint work with Raphael Chesneaux, Zakarya El Khiyati and Jérémie Bec

# Main idea

## How to swim through eddies?

### Process

- ▶ Learn into a "simple fluid flow"
  - ▶ Stationary flow with same shape vortices
- ▶ Select the best swimmer's (strategies)
- ▶ Swim into turbulence with these strokes

## Simpler flagellated swimmer's dynamics

- ▶ Cosserat equation (semi-flexible, inextensible, slender body)

$$\sigma \partial_t^2 \mathbf{X} = \underbrace{\zeta \mathbb{D}^{-1} [\partial_t \mathbf{X} - \mathbf{u}(\mathbf{X}, \mathbf{t})]}_{\text{viscous drag}} + \underbrace{\partial_s (T \partial_s \mathbf{X})}_{\text{tension}} - \underbrace{EI \partial_s^4 \mathbf{X}}_{\text{elasticity}} + \underbrace{f(s, t)}_{\text{locomotion force}}$$

$$\mathbb{D} = \mathbb{I} + \partial_s \mathbf{X} \partial_s \mathbf{X}^T, \quad \zeta = \frac{8\pi\mu}{1 + 2 \log(l/a)}$$

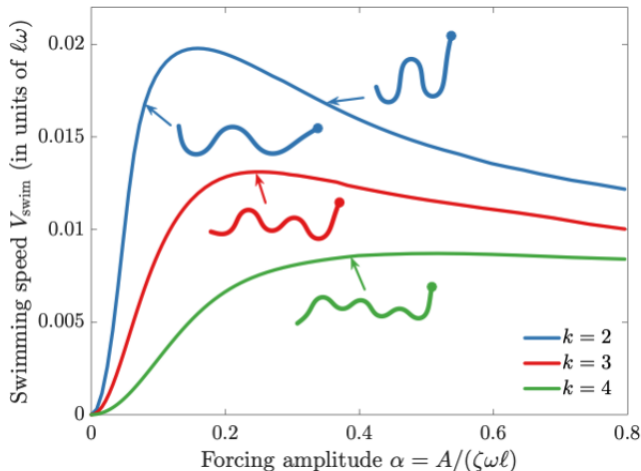

- ▶ Inextensibility constraint  
 $\longleftrightarrow \partial_s \|\mathbf{X}\| = 1$

- ▶ Solving using semi-implicit second-order centred finite difference scheme (see [Tornberg and Shelley (2004)])

## Active locomotion force without an external flow

- ▶ Planar undulation :  $f(s, t) = A \cos(\nu s - \omega t) \mathbf{p}_\perp$
- ▶ No net momentum :  $\nu = \frac{2\pi k}{l}$ ,  $k \in \mathbb{Z}$

## A simple flow : 2D cellular flow

$$\mathbf{u} = \nabla^\perp \mathbf{F} \quad \text{where} \quad \mathbf{F}(\mathbf{x}, t) = \frac{LU}{\pi} \cos(\pi \mathbf{x}_1 / L) \cos(\pi \mathbf{x}_2 / L)$$

$$Re_\alpha \lesssim 1$$

Stable, stationary (cellular/BC/Taylor-Green)

$$\mathbf{u} \propto \nabla^\perp F$$

## Without any strategy - Trap swimmers

- ▶ **Red one** cycles across several cells
- ▶ **Blue one** is stuck between two cells swimming against the flow

# Settings

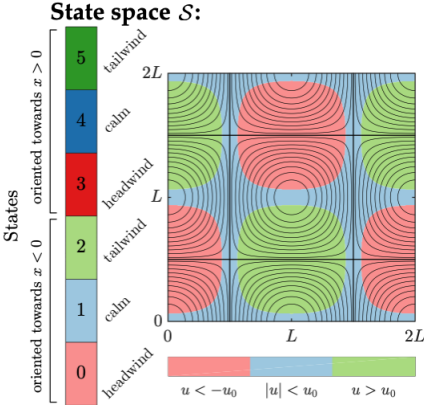

- ▶ Locomotion force : controlling the intensity and the wave direction
- ▶ Navigation problem : move toward  $x > 0$
- ▶ Optimization problem : maximize the speed during a large time

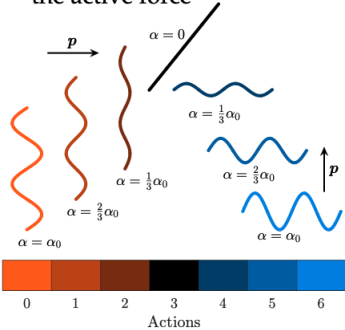

Surfing

**Difficulties** : Although the fluid flow is stationary, the swimmer's dynamics is chaotic.

# Discretize the optimization problem

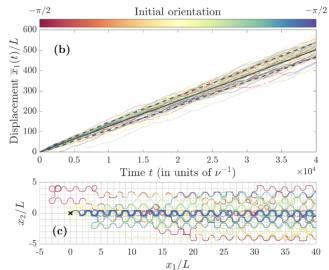

**Space of actions  $\mathcal{A}$ :**  
direction and amplitude of the active force

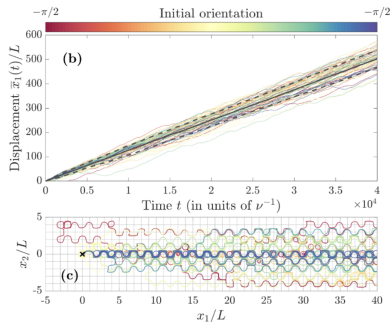

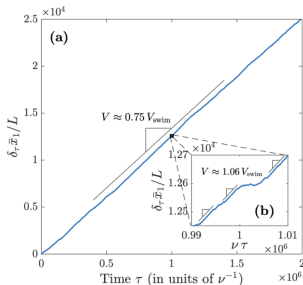

**Policy** : choose action given current state  $(a, s) \in \mathcal{A} \times \mathcal{S} \rightarrow \pi(a, s)$

# Naive strategy

# Performance of the naive strategy

- ▶ Trapping events are no more stable !
- ▶  $\implies$  Naive strategy leads to a positive displacement

## Q-learning

- ▶ The agent in a state  $s(t) \in \mathcal{S}$  decides the action  $a(t) \in \mathcal{A}$   
 $\Rightarrow$  reward  $r(t)$  and enters in  $s(t + \Delta t)$
- ▶ The algorithm maximises an expected future reward  
 $Q : \mathcal{S} \times \mathcal{A} \rightarrow \mathbb{R}$

$$a(t) = \begin{cases} a_* = \arg \max_{\mathcal{A}} Q(s(t), a) & \text{with prob. } 1 - \varepsilon \\ a \neq a_* & \text{with prob. } \varepsilon \end{cases}$$

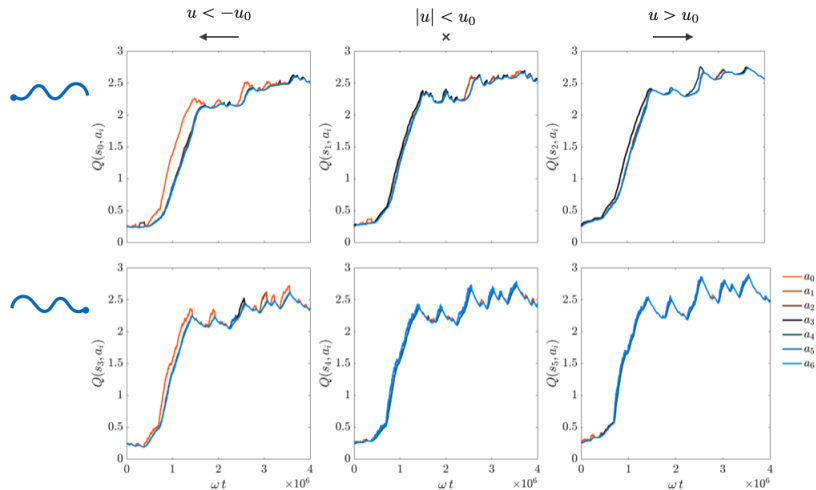

- ▶ The Q-function is updated at each step according to

$$Q^{\text{new}}(s(t), a(t)) = (1 - \lambda)Q(s(t), a(t)) + \lambda \left( r(t) + \gamma \max_{\mathcal{A}} Q(s(t + \Delta t), a) \right)$$

- ▶  $\lambda$  : : learning rate  $\leftrightarrow$  typical time to travel 1 cell
- ▶  $\gamma$  : : discount factor  $\leftrightarrow$  typical time to travel 10 cells
- ▶ Convergence ensured for Markovian decision process with conditions

# Q-learning : no convergence

- ▶ coarse discretization into state and action → Partially observable markov decision process

# Q-learning : no convergence

- Succession of surfing and trapping events

# Select a set of admissible policies

- ▶ Various methods of reinforcement learning (SARSA, Actor-critic) fails
- ▶ Q-learning allows to select "admissible" policies

# Performance a set of admissible policies

- ▶ Mean and Variance of the displacement relatively similar
- ▶ Proba to be trap into one cell is much smaller for 1 and 2

# Robustness with respect to physical parameters

- ▶ Length ratio - Flexibility and Amplitude of the fluid flow

⇒ The performance ranking is not affected in the "red zone"

## Into turbulent flow

$$\text{2D Navier-Stokes } \partial_t \mathbf{u} + \mathbf{u} \cdot \nabla \mathbf{u} = -\nabla \mathbf{p} + \mu \nabla^2 \mathbf{u} - \alpha \mathbf{u} + \nabla^\perp \mathbf{F}, \quad \nabla \mathbf{u} = \mathbf{0}$$

$$Re_\alpha = \frac{U}{\alpha L}$$

$Re_\alpha \lesssim 1$

Stable, stationary (cellular/BC/Taylor-Green)

$$\mathbf{u} \propto \nabla^\perp F$$

$Re_\alpha \gtrsim 1$

Unstable, turbulent

- ▶ Transition to turbulent by increasing  $Re_\alpha$
- ▶ Numerical simulation made by a pseudo-spectral solver

# Robustness into turbulent flow

- ▶ Learned strategies globally work but with increasing effects of trapping

## Summary and perspectives

- ▶ Convergence of  $Q$ -learning algorithms is not granted, certainly due to both **non-Markovianity** and **chaoticity**
- ▶  $Q$ -learning algorithms allow to select some "good" strategies
- ▶ Towards more realistic models
- ▶ → Complex flow
- ▶ → Complex environment
- ▶ ANR NEMO

- ▶ Thanks for your attention.
